1. Make changes to the personal-database project:
   a. get a list of movies and tvseries from all tables using join in a single output
   b. create an enum for genre and accept an array of multiple values. Do this for both TV Series and movies
      Example: genre = ['Action', 'Drama']
   c. For users table, take email-id as input, validate using regex if it is a correct email, if not return error. Then fetch everything using email ids and not using username
   d. Add current timestamp as well while entering data

2. Read about:
   a. # MST branching strategy
   b. # dev, test, production strategy in github
